THE THERMODYNAMICS OF THE GAS TURBINE CYCLE (BRAYTON CYCLE) The conversion of heat released by burning fuel into mechanical energy in a gas turbine is achieved by first compressing air in an air compressor, then injecting and burning fuel at (ideally) constant pressure, and then expanding the hot gas in turbine (Brayton cycle, Figure 3). The turbine

Gas turbines release the Q_2 heat contained in flue gas at temperatures normally ranging between 700 and 900 K. A source of sensible heat at this temperature may be transferred internally in the cycle to heat compressed air between the compressor and the combustor. The schematic of the gas turbine is conceptually simple and is depicted in Fig. 3.16. The only addition to the simple cycle is the insertion of an air/flue gas heat exchanger whose hot side is located after the turbine exhaust ...
